3.2. Permutations	3

## 1. PRELUDE

TODO: Fix notation here...

## 2. INTRODUCTION

In this course we build up the rudiments of some important notions of algebraic structures. That is, an algebraic structure of an arbitrary set, or carrier set, coupled with various finitary operations defined on it. ..

## 3. GROUPS

**Definition 3.1** (Binary operation). A **binary operation** on a set  $\mathcal{G}$  is a map  $\circ : \mathcal{G} \times \mathcal{G} \rightarrow \mathcal{G}$ . **N.B.** that the binary operation is *closed*.

**Definition 3.2** (Magma). A **magma** is a set  $\mathcal{M}$  equipped with a binary operation  $\circ$ . We denote the magma as the tuple pair  $(\mathcal{M}, \circ)$ .

**Definition 3.3** (Semi-group). A **semi-group** is a set  $\mathcal{G}$  equipped with binary operation that is *associative*. Hence, a semi-group is a magma where the operation is *associative*; That is, given any  $x, y, z \in \mathcal{G}$  then  $x \circ (y \circ z) = (x \circ y) \circ z \in \mathcal{G}$ . We denote the semi-group as the tuple pair  $(\mathcal{G}, \circ)$ , not to be confused with a magma from context.

**Definition 3.4** (Monoid). A **semi-group with identity** or, **monoid** for short, is a semi-group  $(\mathcal{G}, \circ)$  with a unique identity element  $e \in \mathcal{G}$  such that  $x \circ e = x = e \circ x \forall x \in \mathcal{G}$

**Example 3.5.** Given  $\mathcal{G} = \mathbb{Z}$  with the binary law of composition  $\circ$  to be defined as arithmetic addition  $+$ . Then,  $(\mathbb{Z}, +)$  forms a semi-group with identity 0. Verify the axioms.

**Definition 3.6** (Group). A **group** is a monoid where every element has an inverse. A **abelian group** is a group that is commutative.

**3.1. Non-commutative groups.** A common class of non-commutative groups are transformation groups. Note:

**Definition 3.7** (Transformation). A bijective map  $\varphi : X \rightarrow X$  is called a **transformation** of  $X$ .

*Note.* The most trivial case is the *identity map*  $id_X$  by  $id_X(x) = x, \forall x \in X$ .

Hence, there exists an inverse  $\varphi^{-1}$  of  $\varphi$  such that  $\varphi^{-1} \circ \varphi = id_X = \varphi \circ \varphi^{-1}$ . Now, take two transformations of  $X$ ,  $\varphi$  and  $\psi$ , and let the product  $\varphi \circ \psi$  be well defined. Then the set of all transformations of  $X$  form the group **Transf(X)**. Since, given  $\varphi, \psi, \phi \in Transf(X)$  then we have associativity,  $\varphi \circ (\psi \circ \phi) = (\varphi \circ \psi) \circ \phi$ . We have identity  $e = id_X \in Transf(X)$  and so, inverses  $\forall \varphi \in Transf(X) \exists ! \varphi^{-1} : \varphi \circ \varphi^{-1} = e$ . Closure follows from the composition of two transformations  $\varphi$  and  $\psi$ , since  $(\varphi \circ \psi)^{-1} = \psi^{-1} \circ \varphi^{-1}$ .

A transformation group is a type of group action which describes symmetries of objects. More abstractly, since a group  $\mathcal{G}$  is a category with a single object in which every morphism is bijective. Then, a group action is a *forgetful functor*  $\mathcal{F}$  from the group  $\mathcal{G}$  in the category **Grp** to the set category **Set** that is,  $\mathcal{F} : \mathcal{G} \rightarrow \mathbf{Set}$ .

That is, for a group  $\mathcal{G}$  and set  $X$ , a group action is defined as a group homomorphism  $\varphi$  from  $\mathcal{G}$  to the symmetric group of  $X$ . The action assigns a permutation of  $X$  to each element of the group in such a way that the permutation of  $X$  assigned to:

- The identity element  $e \in \mathcal{G}$  is the identity transformation of  $X$ , that is,  $id_X$ ;
- A product  $\varphi \circ \psi \in \mathcal{G}$  is the composite of the permutations assigned to  $\varphi$  and  $\psi$ .

Given that each element of  $\mathcal{G}$  is represented as a permutation. Then a group action can also be consider as a permutation representation.

**3.2. Permutations.** Now take a finite set  $X$  with  $|X| = n$ , then the transformations of  $X$  are called **permutations** of the elements of  $X$ . In particular, the group of permutatons of  $X = \{1, 2, \dots, n\}$  is a **symmetric group** of *order*  $n$ , denoted  $S_n$  with **order**  $|S_n| = n!$ . Thus, by taking any subgroup of  $S_n$  we have a **permutation group**. Also note that, for finite sets, *permutations* and *bijective maps* refer to the same operation, namely rearrangement of elements of  $X$ .

A permutaton  $\sigma \in S_n$  can be notated by,

$$\sigma = \begin{pmatrix} 1 & 2 & \cdots & n \\ a_1 & a_2 & \cdots & a_n \end{pmatrix} \text{ where } a_1 = \sigma(1), a_2 = \sigma(2), \dots$$

The identity permutation  $id_n \in S_n$  is simply,

$$id_n = \begin{pmatrix} 1 & 2 & \cdots & n \\ 1 & 2 & \cdots & n \end{pmatrix}$$

Since  $|S_n| = n!$  then the total number of ways  $n$  elements maybe permuted is  $n!$ .

Take any two permutations  $\sigma, \pi \in S_n$  then composition is well defined as **functional composition** as follows.

Given,

$$\sigma = \begin{pmatrix} 1 & 2 & \cdots & n \\ a_1 & a_2 & \cdots & a_n \end{pmatrix} \text{ and } \pi = \begin{pmatrix} a_1 & a_2 & \cdots & a_n \\ b_1 & b_2 & \cdots & b_n \end{pmatrix}$$

then,

$$\begin{aligned} \pi \circ \sigma &= \begin{pmatrix} 1 & 2 & \cdots & n \\ \pi(a_1) & \pi(a_2) & \cdots & \pi(a_n) \end{pmatrix} \\ &= \begin{pmatrix} 1 & 2 & \cdots & n \\ b_1 & b_2 & \cdots & b_n \end{pmatrix} \end{aligned}$$

A inverse of any permutation  $\sigma \in S_n$  is given by,

$$\sigma^{-1} = \begin{pmatrix} 1 & 2 & \cdots & n \\ a_1 & a_2 & \cdots & a_n \end{pmatrix}^{-1} = \begin{pmatrix} a_1 & a_2 & \cdots & a_n \\ 1 & 2 & \cdots & n \end{pmatrix}$$
